Characterization and corrosion behaviours of AISI 316 in hydrochloric environment at various concentrations

ABSTRACT

Characterization and corrosion behaviours of austenitic stainless steel (AISI 316) types at various concentrations of hydrochloric acid solutions were investigated in relation to its pitting corrosion resistance. Both gravimetric-weight loss and potentiodynamic polarization were used for the investigations. The AISI 316 was characterized by X-ray fluorescent (XRF). The characterization of the coupon before and after the corrosion test in various concentrations was done using scanning electron microscopy (SEM). The temperature, acid concentration and time were varied in the range of 30-60°C at 10°C interval, 0.5-2M at 0.5M interval and 1 to 6 day at 1day interval, respectively. The XRF revealed some important elements in the AISI 316 such as (Cr, Ni, Mn, Si, C, S, P etc) which confirmed the materials to AISI 316. The weight loss results revealed that the corrosion rate decreased with increase in exposure time from day 1 to day 6. The corrosion rate of the AISI 316 increased with increase in temperature, severe to pits formation and growths with increase in concentration of acid from 0.5 – 2M. The corrosion rate of AISI 316 increases with increase in acid concentrations. The Tafel results also revealed that both anodic and cathodic sites were shifted with the lowest corrosion resistance occurring at 0.5M of HCl. The SEM of the coupons in the presence of acid revealed pits formation, growths and pitted AISI 316 surfaces. The results obtained from the weight loss, Tafel and characterization were also in good agreement.

Keywords: Austenitic AISI 316, Characterization, Corrosion Behavior, Pitting, Resistance, HCl solution, Tafel.

1. INTRODUCTION

The world demand for fossil fuels is still growing even though alternatives to such energy are currently being sought out globally. The consumptions of oil and natural gas account for over 60% of all global energy demands. It is obvious that the conventional method of extracting fossil fuels will not cease within the next few decades [1]. For years, corrosion has been a major problem in various industries especially in oil and gas and has caused approximately 80-90% failures in this sector [2].

Corrosion occurs in different forms in structures made of steels during service in various environments. These forms of corrosion can be intergranular, pitting, sulphide stress cracking, and stress corrosion cracking. The consequences of these forms of corrosion are obvious, varying from huge material losses to unhealthy environment [3]. However, corrosion cannot be avoided completely, but it can be controlled and prevented by using suitable methods such as cathodic protection, anodic protection, metallic coating, alloying, using inhibitors combinations thereof have been successfully developed to extend the service lifespans of these structures in such corrosive environments [4].

The corrosion behaviours of stainless steel and other metals in acidic environments has been studied by many researchers. Austenitic stainless steels have been used successfully in many applications in both acidic and marine environ-

ments [5-10]. Stainless steels are widely known which have been applied in various industries and environments. However, stainless steel (AISI 316) is the most common material used in a severe corrosive environment such as chloride, hydrochloric acids.

The stainless steel 316 is being classified as low-carbon austenitic stainless steel. The corrosion resistance of this stainless steel is classified as fair to good in various environments and expensive materials [11]. Austenitic stainless steels have a wide spectrum of resistance to corrosion by chemical environment due to the formation of protective passive film on its surface. This film is very thin, essentially transparent and self-healing. If it is damaged mechanically or chemically, it will reform very rapidly [12]. However, the passive films are susceptible to breakdown in the presence of chloride ion, causing pitting corrosion. Pitting corrosion being classified as very dangerous threat and produces pit which looks small on surface but propagate deep inside the metals. This type of corrosion is considered more harmful than uniform attack. The corrosion rate of pitting corrosion is 10-100 times faster than uniform corrosion [13].

Therefore, the aim of this work is to characterize and determine the corrosion resistance of AISI 316 in different concentrations (0.5M, 1M, 1.5M, and 2M) of hydrochloric acid and temperature between 30-60°C solutions using weight loss and potentiodynamic measurement test.

2. EXPERIMENTAL DETAIL

2.1. Materials

The AISI 316 coupon used for this study was obtained from a steel manufacturer company in Port Harcourt, Rivers State. The chemical composition analysis conducted on the sample was carried at Spectro Ametek, Materials Analysis Division, Lagos.

2.2. Hydrochloric acid Solutions

0.5 M hydrochloric acid was prepared by using the following equation:

$$C_1 = \frac{\% \text{ purity of acid} \times \text{density} \times 10}{\text{molar mass of acid}} \quad (1)$$

Where: % purity of HCl acid = 37%

Density of HCl = 1.19g/cm³ and molar mass of acid = 36.46g/mol

Thus, the concentration of stock from which the 0.5 M hydrochloric acid and solution was prepared from is 12.08M.

The quantity (volume) of the stock needed is then estimated by using the relation:

$$C_1 V_1 = C_2 V_2 \quad (2)$$

Where:

C_1 = concentration of the stock,

C_2 = the required molarity of the acid (0.5 M),

V_1 = volume of stock solution needed to prepare the 0.5 M acid and

V_2 = volume of acid required (1000cm³)

$$V_1 = \frac{C_2 V_2}{C_1} \quad (3)$$

Therefore, about 41.5 cm³ of the stock was made up to 1000 cm³ in a litre standard flask to obtain the 0.5M concentration of HCl acid solution. The same procedures were used in producing 1M, 1.5M and 2M concentrations respectively. All the test solutions used in the work were based on molarity and prepared from the above chemicals and conductivity water.

2.3. Samples Preparation

All specimens were mechanically polished to a mirror like finish using emery papers with increasing grit sizes (100, 180, 400, 500, 600, 800, 1000), and degreased using acetone, before start the experiments. Austenitic stainless steels samples were cut into 1cm x 1cm plates and later washed, dried and stored in a desiccator for the weight loss analyses.

2.4. Weight Loss Measurements

The weight loss experiments were carried out in accordance with the methods reported elsewhere [14-18]. Previously polished and degreased specimens of size 20 mm by 10 mm coupons were used for weight loss studies. Already-weighed specimens were separately immersed in 500 milliliters (ml) of 0.5M, 1M, 1.5M and 2M HCl solutions for 1, 2, 3, 4, 5 and 6 days respectively. After the elapsed time, the specimens were taken out, washed, dried and reweighed. All the experiments were performed in triplicate, and average values were recorded. Seventy-two (72) samples were used and three samples were withdrawn every day for six (6) days. The experiment was carried out at four different temperatures of 30, 40, 50, and 60°C. From the measured weight loss data, the corrosion rates (m/y) (CR) were calculated using Equation 4 [19, 20]:

$$CR = \frac{534 W}{DAT}, \text{ mpy} \quad (4)$$

Where W, D, A and T were units of milligrams, grams per cubic centimeter, square inches and hours respectively.

2.5. Potentiodynamic polarization studies

The potentiodynamic polarization studies were carried out with a three electrode configuration. The specimens were embedded in epoxy resin and the exposed surface area of the AISI 316 working electrode was 1.24 cm². The working surface area was subsequently ground with grinding papers from 600 down to 1800 grit, cleaned by distilled water and ethanol. The solutions of 0.5 M-2M HCl were prepared by dilution of an analytical reagent grade with doubly distilled water. Potentiodynamic polarization measurements were done using an Autolab potentiostat (PGSTAT30 computer controlled) with the General Purpose Electrochemical Software (GPES) package version 4.9. Potentiodynamic anodic and cathodic polarization curves were obtained with a scan rate of 2 mv/s in the potential range from -0.2 to -0.8 mv relative to the corrosion potential (E_{corr}). Values of the corrosion current density (I_{corr}) were obtained by extrapolation of the cathodic branch of the polarization curve back to E_{corr} . From the polarization curves, Tafel slopes, corrosion potential and corrosion current

were then calculated. All the tests were performed at ambient temperature (30°C) in a static solution [21].

2.6. Characterization of the Coupons

The AISI 316 surface was prepared for SEM studies by taking the specimens from each concentration (0.5, 1, 1.5 and 2M) at the optimum concentrations of the acid. The AISI 316 specimens were then washed with distilled water, dried and analyzed using SEM. A Philips model XL30SFEG scanning electron microscope was used for the surface analysis [22].

3. RESULTS AND DISCUSSION

3.1. Chemical Composition of the Coupon

The chemical composition analysis conducted on AISI 316 coupon used for this study was carried out at Spectro Ametek, Materials Analysis Division, Lagos. The composition of metal sample in weight % are presented in table 1 while the rest is iron.

Table 1. Chemical composition of AISI 316

Tabela 1. Hemijski sastav AISI 316

Grade	Cr	Mn	Mo	S	Ni	N	Si	V	P	C
AISI 316	18.20	1.24	0.137	0.008	8.28	0.052	0.500	0.0913	0.033	0.043

3.2. Weight Loss and Potentiodynamic Polarization Measurements

3.2.1. Effect of time

Weight loss measurements were performed on AISI 316 coupons immersed in 0.5, 1, 1.5, and 2 M HCl solutions at different temperatures 30 °C for 6 days were carried out. Figure 1 presented variation in corrosion rate against exposure time for AISI 316

immersed in 0.5M HCl. It was observed that there was decrease in corrosion rate as exposure time increases [25]. This is because there was no space for direct contact between metal surface and corrosive ions by corrosion products and excess of cations near the metal surface as reaction proceeds. This is also in consonance with findings of [26].

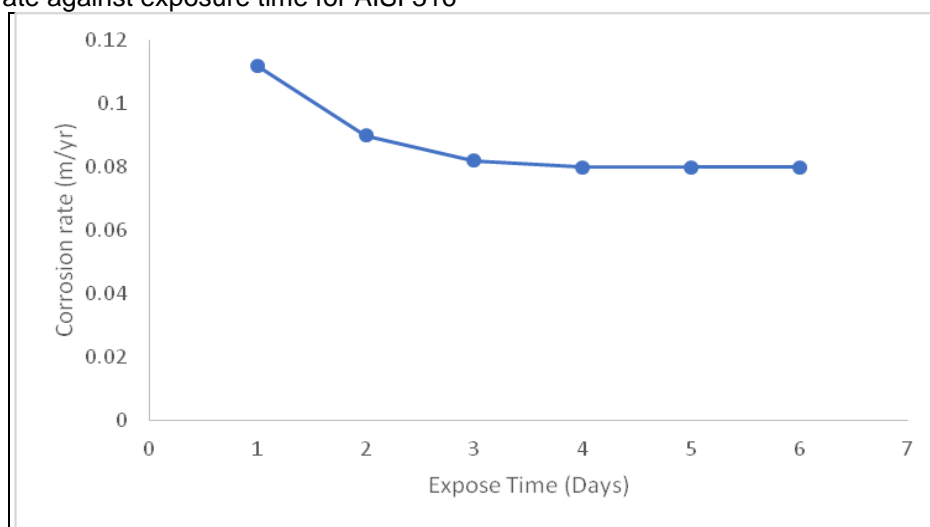

Figure 1. Variation of corrosion rate against exposure time for AISI 316 immersed in 0.5M HCl

Slika 1. Varijacija brzine korozije u odnosu na vreme izlaganja za AISI 316 uronjenog u 0,5M HCl

3.2.2. Effect of Concentrations

Figure 2 shows an increase in corrosion rate as the concentration of the HCl increases from 0.5 – 2M. The results also show a corrosion rate of 0.2 m/year at 0.5M, 0.08 m/year at 1M, 0.09 m/year at 1.5M, and 0.112 m/year at 2M of HCl. This indicates high resistance to corrosion at 0.5 M. The high chromium content which forms chromium oxide passivation on the surface of AISI 316 protects

it initially. The 8.24% nickel contained in the AISI 316 also assists in providing resistance to uniform corrosion in moderate reducing environment of HCl at low concentrations. However, as the concentration of the HCl increases, the corrosion rates decrease. Both the chromium oxide and nickel were exposed that offered protection were destroyed by the acid which was responsible for increase in corrosion rates and also agreed to the findings of [27].

Slika 2. Varijacija brzine korozije u odnosu na koncentraciju za AISI 316 uronjenog u različitim koncentracijama HCl

3.2.3. Effect of temperature on corrosion of AISI 316

Figure 3 showed the variation of corrosion rate against temperature for AISI 316 immersed in HCl. From the table, there was an increase in corrosion rate as the temperature increases at the concentrations investigated. This is due to increased rate of

dissolution process of AISI 316 of the metal surface at high temperature [28]. In an acidic solution the corrosion rate is related to temperature by the Arrhenius equation and the log of corrosion rate is a linear function of temperature which agreed with the findings of [29].

Figure 3. Variation of corrosion rate against temperature for AISI 316 immersed in HCl

Slika 3. Varijacija brzine korozije u odnosu na temperaturu za AISI 316 uronjenog u HCl

3.3. Potentiodynamic polarization (Tafel) curves

Potentiodynamic polarization curves obtained for different concentrations of the hydrochloric acid are given in figure 4. The potentiodynamic polarization studies revealed that the corrosion current density (i_{corr}) markedly increased with the increase in the concentration of the acid. However, the corrosion potential shifted to high negative values upon increase of the acid concentration. The values of anodic and cathodic Tafel slopes

were changed indicating that this behaviour reflects the acid concentration ability to initiate pits formation to pits growths as the concentrations of acid increase from 0.5-2M on both anodic and cathodic sites. The behaviour reflects the acid ability to cause pits corrosion in AISI 316 on anodic and cathodic sites [24]. It was observed that with increase in concentration of the acid from 0.5 to 2M, the maximum corrosion rate was observed for the concentration of 2M of the HCl [27,28].

Slika 4. Potenciodinamičke polarizacije krive za AISI pri različitim koncentracijama u rastvorima HCl na 30 °C

3.4. Surface Morphology of AISI 316 at Different concentrations

The morphology of AISI 316 samples as-received and at different concentrations in hydrochloric acid solutions were presented in plates 1-5. Plate 1 presented the surface morphology of as-received.

Plate 2 showed samples in 0.5M HCl solution, where pits initiation commenced which is often linked to the presence of local defects at the metal surface such as flaws in the oxide or segregation of alloying elements, presence of aggressive anions such as chlorides in the environment.

Plate 1. SEM microstructure of as-received AISI 316

Ploča 1. SEM mikrostruktura primljenog AISI 316

Plate 2. SEM microstructure of AISI 316 in 0.5M HCl

Ploča 2. SEM mikrostruktura AISI 316 u 0.5M HCl

Pit initiation occurs on the alloy surface passivated by an oxide film due to the damage caused by passivation of the electrolyte resulting in anodic reaction on the metal surface while the unexposed protective surrounding becomes the cathode leading to localized corrosion. Plates 3-5 showed the morphologies of AISI 316 in HCl at different concentrations of 1M, 1.5M and 2M respectively. At these concentrations, growth of pits

increases as the concentrations of the acid increases and more pitted AISI 316 were seen especially in plates 4 and 5. From the SEM evaluation, it is clear that as the concentrations of the hydrochloric acid increases, the corrosion resistance increases which confirmed the Tafel results obtained earlier and similar to the findings of [2,4,6,8].

Ploča 3. SEM mikrostruktura AISI 316 u 1M HCl

Plate 4. SEM microstructure of AISI 316 in 1.5M HCl

Ploča 4. SEM mikrostruktura AISI 316 u 1.5M HCl

Plate 5. SEM microstructure of AISI 316 in 2M HCl

Ploča 5. SEM mikrostruktura AISI 316 u 2M HCl

4. CONCLUSION

The following conclusions can be drawn from the results obtained:

1. The corrosion rate decreased with increase in exposure time from day 1 to day 6.

2. The corrosion rate of the AISI 316 increased with increase in temperature and was subjected to pits corrosion.

3. From the Tafel graphs and characterization results, the rank of potential at various hydrochloric

acid concentrations from the highest to the lowest were 0.5M, 1M, 1.5M and 2M with hydrochloric acid respectively. Therefore, the lowest corrosion resistance of AISI was at 0.5M.

4. The degree of pits formation and growths increases with increase in acid concentrations of HCl and the results obtained from the Tafel and characterization are in good agreements.

IZVOD

Karakterizacija i korozijsko ponašanje aisi 316 u hidrohlornoj okolini pri različitim koncentracijama

Ispitivane su karakteristike i korozijsko ponašanje vrsta austenitnog nerđajućeg čelika (AISI 316) u različitim koncentracijama rastvora hlorovodonične kiseline u odnosu na njegovu korozijsku otpornost. Za istraživanje su korišćeni gravimetrijski gubitak težine i potenciodinamička polarizacija. AISI 316 je okarakterisan pomoću rendgenski fluorescentnog analizatora (KSRF). Karakterizacija uzoraka pre i posle korozijskog testa u različitim koncentracijama izvršena je pomoću skenirajuće elektronske mikroskopije (SEM). Temperatura, koncentracija kiseline i vreme varirali su u rasponu od 30-60°C u intervalu od 10°C, 0,5-2M na intervalu 0,5M i 1 do 6 dana u intervalu od jednog dana, respektivno. Pomoću KSRF otkriveni su neki važni elementi u AISI 316, kao što su (Cr, Ni, Mn, Si, C, S, P itd) koji su potvrdili tačnost materijala AISI 316. Rezultati gubitka težine otkrili su da se stopa korozije smanjivala s povećanjem vremena izlaganja od jedan do šestog dana. Brzina korozije AISI 316 povećavala se sa porastom temperature, teškim za formiranje rupa, i rasla je sa povećanjem koncentracije kiseline od 0,5 - 2M. Brzina korozije AISI 316 raste sa povećanjem koncentracije kiseline. Rezultati Tafelih krivi, takođe, su otkrili da su i anodna i katodna mesta pomerena sa najmanjom otpornošću na koroziju koja se pojavljuje pri 0,5M HCl. SEM uzorka u prisustvu kiseline otkrio je formiranje jama i narasle površine AISI 316. Rezultati dobijeni merenjem gubitka težine, Tafel-om i karakterizacijom su se takođe dobro slagali.

Ključne reči: Austenitni AISI 316, karakterizacija, ponašanje korozije, pitting, otpornost, rastvor HCl, Tafel.
